

REAL-TIME POLYMERASE CHAIN REACTION-BASED  
GENOTYPING ASSAY FOR SINGLE NUCLEOTIDE POLYMORPHISM

5

Cross-reference to Related Application

10           This application claims benefit of provisional patent  
application U.S. Serial No. 60/457,512, filed March 25, 2003, now  
abandoned.

BACKGROUND OF THE INVENTION

15

Field of the Invention

          The present invention relates generally to the field of  
single nucleotide polymorphism genotyping. More specifically, the  
present invention provides a real-time polymerase chain reaction-  
20   based genotyping assay for the detection of single nucleotide  
polymorphisms.

### Description of the Related Art

P-glycoprotein (P-gp), a member of the large adenosine triphosphate-binding (ATP-binding) cassette superfamily of transport proteins also called traffic ATPases, is the product of the human multidrug resistance gene (*MDR1*). P-glycoprotein is highly expressed on the apical (luminal) surface of organs that have excretory functions, such as the bile canalicular membrane of hepatocytes and the renal proximal tubule. Moreover, P-glycoprotein is significantly expressed on the luminal surface of tissues that serve as barriers, such as the brush border of the small intestine and the capillary endothelial cells of the blood-brain barrier.

Tissue distribution suggests that P-glycoprotein protects the body from toxic xenobiotics by secreting them into the bile, urine, and intestinal lumen and by reducing their accumulation in the brain and testes. As a result, interindividual variability in the disposition of numerous drugs has been ascribed to differences in P-gp expression. It has been reported that intestinal P-glycoprotein expression accounted for approximately 30% of interindividual

variability in the maximal plasma concentration after oral administration of cyclosporine.

A novel P-glycoprotein aberrant allele, *MDR1*\*2, linked to 2 synonymous single nucleotide polymorphisms (SNPs) (C1236T in  
5 exon 12 and C3435T in exon 26) and a nonsynonymous single nucleotide polymorphism in exon 21 (G2677T, Ala893Ser) was recently described (Kim et al., 2001). The single nucleotide polymorphisms found on exons 12, 21, and 26 are not strictly allelic; however, they exhibit strong linkage disequilibrium and  
10 account for a majority of the described haplotypes (Kim et al., 2001; Tang et al., 2002). *MDR1*\*2 was found to be associated with altered fexofenadine disposition. Individuals carrying 2 wild type alleles (\*1/\*1) had a 40% greater fexofenadine systemic exposure after oral administration compared with individuals heterozygous or  
15 homozygous for *MDR1*\*2. Reduced fexofenadine systemic exposure in carriers of the *MDR1*\*2 allele potentially results in reduced therapeutic benefit after oral administration of fexofenadine.

Kim et al. (2001) reported significant ethnic differences in *MDR1*\*2 allelic frequency, with 62% and 13% of European  
20 Americans and African Americans, respectively, carrying at least one *MDR1*\*2 allele. Thus, polymorphic MDR1 expression may contribute

to interracial variability in drug disposition. Unfortunately, attempts to determine the association between polymorphic P-glycoprotein expression and drug disposition have yielded equivocal results.

5           To facilitate clarification of the significance of commonly occurring *MDR1* single nucleotide polymorphisms and their ethnic frequency on drug disposition, a rapid and robust polymerase chain reaction-based (PCR-based) screening method for the single nucleotide polymorphisms C3435T and G2677T would be  
10 highly desirable. The present invention fulfills this longstanding need and desire in the art.

## 15                           SUMMARY OF THE INVENTION

The present invention provides a real-time polymerase chain reaction (PCR)-based method to detect single nucleotide polymorphisms. Discrimination between wild type and mutant  
20 alleles was achieved using PCR amplification of specific alleles modified to prevent non-Watson Crick base pairing (Okimoto &

Dodgson, 1996; Sommer et al., 1992; Bottema et al., 1993; Newton et al., 1989). Two key nucleotide mismatches are required for allelic discrimination. The first nucleotide difference between primers used to discriminate between wild type and mutant alleles was located at the 3' terminal base. However, a single base pair difference at the 3' end of the primer is insufficient, in most cases, to achieve allelic discrimination. An additional internal nucleotide mismatch (typically within 5 base pairs of the 3' end) is required for specific amplification of either the wild-type or mutant allele. Thus, a second nucleotide mismatch located three bases from the 3' end for both the wild-type and mutant-specific primers was included to generate an internal primer/template mismatch that prevents amplification of the nonmatching primer.

In one embodiment, the present invention provides a genotyping assay to detect *MDR1* (human multidrug resistance gene) single nucleotide polymorphisms (SNPs) C3435T and G2677T. C3435T and G2677T are linked to *MDR1*\*2, which is associated with enhanced efflux activity *in vitro* and *in vivo*. PCR reactions for genotyping C3435T and G2677T using allele-specific primers were conducted in separate tubes. PCR amplification was monitored by Smart Cycler (Cepheid, Sunnyvale, CA) using SYBR<sup>TM</sup> Green I, a non-

specific double stranded DNA intercalating fluorescent dye. PCR growth curves exceeding the threshold cycle were considered positive. Fluorescence melt-curve analysis was used to corroborate results from PCR growth curves.

5           Using PCR growth curves, the assay disclosed herein accurately determined hetero- and homozygosity for C3435T and G2677T. Genotype assignments based on PCR growth curve, melt-curve analysis, agarose gel electrophoresis, and direct DNA sequencing results of PCR products were in perfect agreement.

10   Thus, the present invention provides a rapid *MDR1* genotyping method that can be used to assess the contribution of *MDR1*\*2 to pharmacokinetic and pharmacodynamic variability of P-gp substrates.

          In another embodiment, the above described real-time

15   PCR-based method was used to detect cytochrome P-450 3A5 (*CYP3A5*) single nucleotide polymorphisms *CYP3A5*\*3 (A22893G) and *CYP3A5*\*6 (G30597A).

          Other and further aspects, features, and advantages of the present invention will be apparent from the following

20   description of the presently preferred embodiments of the

invention. These embodiments are given for the purpose of disclosure.

5

## BRIEF DESCRIPTION OF THE DRAWINGS

**Figures 1A-D:** *MDR1* C3435T allelic discrimination by real-time analysis using the Smart Cycler. Plot of fluorescence versus cycle number using human genomic DNA obtained from individuals with CC (**Figure 1A**), TT (**Figure 1B**), or CT (**Figure 1C**) genotypes and nontemplate control (**Figure 1D**). Interrogation for the presence of either the C or T allele was conducted in physically separate tubes using the common reverse primer 3435R coupled with either the wild type specific primer 3435W (—◆—, blue) or the mutant-specific primer 3435M (—●—, pink). PCR growth curves that exceed the threshold fluorescence indicate specific PCR product formation.

**Figures 2A-D:** Melt curve analysis of PCR products using SYBR<sup>TM</sup> Green I. Melt curves were converted to melt peaks by plotting the negative first derivative of the fluorescence versus temperature ( $[-dF/dt]$ ). Plot of  $[-dF/dt]$  versus temperature

obtained after amplification of CC (Figure 2A), TT (Figure 2B), CT (Figure 2C) genomic DNA and nontemplate control (Figure 2D) using the common reverse primer 3435R coupled with either the wild type specific primer 3435W or the mutant-specific primer 3435M. The melt temperature ( $T_m = 84^\circ\text{C}$ ) was identical for PCR products formed using either the wild type or mutant-specific primers.

**Figure 3:** *MDR1* C3435T allelic discrimination by conventional modified allele-specific PCR. An ethidium bromide-stained 2% agarose gel containing PCR fragments (134 bp) was run to confirm real-time PCR results. Odd-numbered lanes contain PCR fragments after amplification with 3435R and 3435W. Even-numbered lanes contain PCR fragments after amplification with 3435R and 3435M. PCR products amplified from genomic DNA with different 3435 genotypes were loaded as follows: CC (lanes 1 and 2), TT (lanes 3 and 4), and CT (lanes 5 and 6). Lanes 7 and 8 represent nontemplate controls. Lane marker contains a 100-bp DNA ladder.

**Figure 4A-C:** CYP3A5 allelic discrimination using human genomic DNA as template. Human genomic DNA obtained from individuals with \*1/\*1 (Figure 4A), \*3/\*3 (Figure 4B), or \*1/\*3 (Figure 4C) genotype interrogated for the presence of either the \*1

or \*3 allele using wild-type (—◆—, blue) and mutant-specific (—◆—, orange) primers.

**Figures 5A-C:** Melting curve analysis of PCR products using SYBR™ Green I. Negative first derivative of fluorescence versus temperature curves for PCR products obtained after amplification of \*1/\*1 (Figure 5A), \*3/\*3 (Figure 5B), or \*1/\*3 (Figure 5C) genomic DNA using wild-type (—◆—, blue) and mutant-specific (—◆—, orange) primers.

10

## DETAILED DESCRIPTION OF THE INVENTION

Fluorescence-based single nucleotide polymorphism detection assays offer several important advantages over traditional PCR approaches used to determine genotype (e.g. sequencing of PCR products and restriction fragment length polymorphism, RFLP). First, RFLP can in some instances result in significant false positive rates as a result of incomplete restriction enzyme digestion or the presence of other mutations close to the mutation of interest.

20 Second, fluorescence-based genotyping assays are more amenable to

high-throughput screening, as they do not require extensive post-amplification manipulation.

Commonly used fluorescence-based PCR techniques for single nucleotide polymorphism detection include the use of either the nonspecific DNA intercalating dye SYBR™ Green I or an allele-specific fluorogenic probe (i.e. Taqman). In many instances, the use of SYBR™ Green I is more cost-effective when applied to haplotype analysis of genes with multiple allelic variants since it does not require the synthesis of numerous allele-specific fluorogenic probes.

In the present invention, the use of allele-specific primers containing an additional internal mismatch obviates the need for extensive optimization of PCR amplification conditions associated with traditional PCR amplification of specific alleles. The inventors have successfully applied the approach described here to genotype 11 other single nucleotide polymorphisms using, in most instances, identical PCR amplification conditions.

Current methods for genotyping *MDR1* or *CYP3A5* include PCR amplification followed by sequencing and fluorogenic probe-based PCR assays. The simple, rapid, inexpensive, reproducible, and reliable real-time PCR genotyping methods presented here constitute a significant improvement over current

techniques. Using this approach, genotyping results can be obtained within 2 hours of whole blood or tissue procurement. Importantly, these techniques are also applicable in laboratories lacking access to real-time PCR equipment since allelic discrimination can be  
5 determined using traditional PCR and agarose gel electrophoresis.

Thus, the present invention is directed to a method of genotyping *MDR1* single nucleotide polymorphism C3435T, comprising the step of amplifying DNA samples with primers SEQ ID NOs: 1 and 3 or SEQ ID NOs: 2 and 3. The presence of DNA products  
10 amplified by primers SEQ ID NOs: 2 and 3 would indicate the individual has the genotype C3435T. In general, the amplified DNA products can be identified by real-time fluorescence-based analysis, melt curve analysis or gel electrophoresis. In the case of gel electrophoresis, the presence of a 134 base pairs product  
15 corresponds to genotype C3435T.

In another embodiment, there is provided a method of genotyping *MDR1* single nucleotide polymorphism G2677T, comprising the step of amplifying DNA samples with primers SEQ ID NOs: 4 and 6 or SEQ ID NOs: 5 and 6. The presence of DNA products  
20 amplified by primers SEQ ID NOs: 5 and 6 would indicate the individual has the genotype G2677T. In general, the amplified DNA

products can be identified by real-time fluorescence-based analysis, melt curve analysis or gel electrophoresis. In the case of gel electrophoresis, the presence of a 216 base pairs product corresponds to genotype G2677T.

5                   In yet another embodiment, there is provided a method of genotyping human cytochrome P-450 3A5 single nucleotide polymorphism CYP3A5\*3, comprising the step of amplifying DNA samples with primers SEQ ID NOs: 11 and 13 or SEQ ID NOs: 12 and 13. The presence of DNA products amplified by primers SEQ ID  
10 NOs: 12 and 13 would indicate the individual has the genotype CYP3A5\*3. In general, the amplified DNA products can be identified by real-time fluorescence-based analysis, melt curve analysis or gel electrophoresis. In the case of gel electrophoresis, the presence of a 238 base pairs product corresponds to genotype CYP3A5\*3.

15                   In still yet another embodiment, there is provided a method of genotyping human cytochrome P-450 3A5 single nucleotide polymorphism CYP3A5\*6, comprising the step of amplifying DNA samples with primers SEQ ID NOs: 14 and 16 or SEQ  
ID NOs: 15 and 16. The presence of DNA products amplified by  
20 primers SEQ ID NOs: 15 and 16 would indicate the individual has the genotype CYP3A5\*6. In general, the amplified DNA products can be

identified by real-time fluorescence-based analysis, melt curve analysis or gel electrophoresis. In the case of gel electrophoresis, the presence of a 273 base pairs product corresponds to genotype CYP3A5\*6.

5           The following examples are given for the purpose of illustrating various embodiments of the invention and are not meant to limit the present invention in any fashion. One skilled in the art will appreciate readily that the present invention is well adapted to carry out the objects and obtain the ends and advantages  
10 mentioned, as well as those objects, ends and advantages inherent herein. Changes therein and other uses which are encompassed within the spirit of the invention as defined by the scope of the claims will occur to those skilled in the art.

15

#### **EXAMPLE 1**

##### **MDR1 Single Nucleotide Polymorphisms Genotyping**

20           The present example describes a real-time PCR assays for the rapid detection of the *MDR1* single nucleotide polymorphisms C3435T and G2677T. These methods can be readily applied to

investigate the effect of *MDR1* polymorphic expression on pharmacokinetic and pharmacodynamic variability of P-gp substrates.

5

## EXAMPLE 2

### Primer Design

PCR primers are listed in Table 1. Oligonucleotide primers were designed based on the published *MDR1* sequence (Genbank #AC005068) using the online program Primer3. Hairpin structures and primer-dimers were predicted with Oligo Toolkit™. The primers were synthesized by Integrated DNA Technologies (Coralville, IA). Expected amplicon lengths were 216 base pairs (bp) and 134 bp for G2677T and C3435T, respectively. Discrimination between wild type and mutant alleles was achieved using PCR amplification of specific alleles modified to prevent non-Watson Crick base pairing (Okimoto & Dodgson, 1996; Sommer et al., 1992; Bottema et al., 1993; Newton et al., 1989). Briefly, the first nucleotide difference (C or T) between sense primers (3435W and 3435M) used to discriminate between wild type and mutant alleles is located at the 3' terminal base. The second primer base

change (A to G) located 3 bases from the 3' end generates an internal primer/template mismatch, and this prevents amplification of the nonmatching primer. These changes were made to prevent the generation of possible spurious products, which could otherwise occur by the annealing and extension of the 3435W primer to the first-round product of 3435M. A similar strategy was used to achieve allelic discrimination for G2677T (Table 1).

### EXAMPLE 3

#### Real-Time PCR Amplification

The Smart Cycler (Cepheid, Sunnyvale, CA) was used to monitor PCR amplification using SYBR<sup>TM</sup> Green I (Molecular Probes, Eugene, OR), a nonspecific double-stranded DNA intercalating fluorescent dye. Thus, to achieve allelic discrimination between wild type and mutant alleles, two physically separate PCR reactions containing either wild type or mutant-specific primers were performed. All reactions were carried out in a total volume of 25  $\mu$ L. Reaction conditions were identical for G2677T and C3435T except where noted. Each reaction mixture contained a 1:12,500

dilution of SYBR™ Green I nucleic acid gel stain 10,000X in dimethyl sulfoxide (DMSO) (Molecular Probes); 0.2mM of dATP, dCTP, dGTP, and dTTP; 200nM of both forward and reverse primers; 1.0 U of Taq DNA polymerase (Promega, Madison, WI); 6% DMSO; and 20 to 120  
5 ng of genomic DNA in 1X PCR buffer (pH 8.3, 10X solution containing 100mM Tris-HCl, 500mM KCl, 15mM MgCl<sub>2</sub> and 0.01% gelatin) (Sigma, St. Louis, MO). Genomic DNA was obtained from the Human Genetic Cell Repository, sponsored by the National Institute of General Medical Sciences.

10           The amplification program for both G2677T and C3435T consisted of 1 cycle of 95°C with 120-second hold followed by 27 cycles of 95°C with 6-second hold, specified annealing temperature of 62°C with 15-second hold, and 72°C with 20-second hold. After amplification, melt analysis was performed by heating the reaction  
15 mixture from 60°C to 95°C at the rate of 0.2°C/s. A negative control without DNA template was run with every assay to assess the overall specificity. PCR products for sequencing the 2677 locus were generated using the sense primer (5'-AAGATTGCTTTGAGGAATGGT-3', SEQ ID NO:7) and the antisense primer (5'-  
20 GCTATAGGTTCCAGGCTTGCT-3', SEQ ID NO:8). PCR products for sequencing the 3435 locus were generated using the sense primer

(5'-GAGCCCATCCTGTTGACTG-3', SEQ ID NO:9) and the antisense primer (5'-ACTATAGGCCAGAGAGGCTGC-3', SEQ ID NO:10).

5

#### EXAMPLE 4

##### PCR Product Analysis

The real-time fluorescence signal generated by the nonspecific double-stranded DNA binding dye SYBR™ Green I was  
10 analyzed using the Smart Cycler software. A threshold cycle (Ct) was determined for each sample using the exponential growth phase and the baseline signal from fluorescence versus cycle number plots. A sample was deemed positive if fluorescence exceeded the threshold. Threshold fluorescence level was automatically set by  
15 the Smart Cycler software. Melt curves were transformed to the negative first derivative melt curves ( $[-dF/dt]$  vs temperature). In the melt analysis, the negative first derivative peaks, which are characteristic of the PCR product melt temperature, were used to identify specific PCR products. Amplification reactions were  
20 routinely checked for the presence of nonspecific products by agarose gel electrophoresis. PCR products were isolated by

QIAquick (Qiagen, Valencia, CA) after separation by agarose gel electrophoresis and subjected to direct sequencing using the ABI Prism Model 3100 (Applied Biosystems, Foster City, CA). Genomic DNA obtained from individuals determined by sequencing to be homo-, hetero-, and nullizygous for the 2677T and 3435T alleles was used for genotyping assay development and validation.

## EXAMPLE 5

### *MDR1* Genotyping Results

Allele-specific primers containing an additional nucleotide mismatch 3 bases from their 3' termini had little effect on specific PCR product yield. However, nonspecific PCR product yield was drastically reduced to undetectable levels. Consequently, PCR conditions were optimized such that the threshold cycle (Ct) was exceeded only when specific amplification occurred (i.e., only in the presence of a primer:template match). Figure 1A illustrates the results of the *MDR1* C3435T allelic discrimination assay using homozygous 3435C genomic DNA amplified with a common primer

3435R and either the wild-type specific primer 3435W or the mutant-specific primer 3435M. When primers 3435R and 3435W were used to amplify homozygous 3435C genomic DNA, the PCR growth curve exceeded the Ct value at approximately 21 cycles (Figure 1A), and the melt analysis (negative first derivative) yielded a characteristic sharp peak at approximately 84°C for the product (Figure 2A).

PCR growth curves remained at approximately background fluorescence, and no distinct melt analysis peak was noted when primers 3435R and 3435M were used to amplify homozygous 3435C genomic DNA (Figures 1A and 2A). Agarose gel electrophoresis yielded the expected 134-bp fragment when homozygous 3435C DNA was amplified with primers 3435R and 3435W (Figure 3). However, no bands were visualized after homozygous 3435C DNA was amplified using primers 3435R and 3435M (Figure 3). Similarly, allelic discrimination was achieved after amplification of homozygous 3435T DNA using primers 3435R, 3435M, and 3435W (Figures 1B, 2B, and 3).

Overlapping PCR growth curves yielding similar Ct values were obtained when CT genomic DNA was amplified using wild-type and mutant-specific primers (Figure 1C). In addition, a distinct melt

analysis peak was present after amplification with both wild-type and mutant-specific primers (Figure 2C). Results from real-time PCR corroborate conventional PCR results (Figure 3) and accurately predict the presence of both wild-type and mutant 3435 alleles in the heterozygote control.

Figures 1D and 2D illustrate results from nontemplate control reaction. Results obtained from optimization and application of the G2677T genotyping assay to individuals with GG, GT, and TT genotypes were similar to those reported for C3435T (data not shown). Melt analysis yielded a characteristic sharp peak at approximately 80°C (Table 1).

The validity of the present methods was verified by testing 20 individuals (10 Caucasians and 10 African Americans) comprising all 3 G2677T and C3435T genotypes. The genotype distribution was in Hardy-Weinberg equilibrium. The allele frequency for 2677T was 0.50 and 0.15 for Caucasians and African Americans, respectively. The allele frequency for 3435T was 0.55 and 0.20 for Caucasians and African Americans. The allele frequencies for 2677T and 3435T were similar to those previously reported for Caucasians and African Americans. Eighteen samples (3 individuals homo-, hetero-, and nullizygous for either 2677T or

3435T) were sequenced. Sequencing results were in perfect agreement with real-time PCR results.

TABLE 1

Primer Sequences For *MDR1* Genotyping

Primer <sup>a</sup>	Sequence <sup>b</sup>	T <sub>m</sub> <sup>c</sup>
C3435T		84°C
3435W	5' 43288 GTGGTGTACAGGAAGAGGTC 3' 43268 (SEQ ID NO:1)	
3435M	5' 43288 GTGGTGTACAGGAAGAGGTT 3' 43268 (SEQ ID NO:2)	
3435R	5' 43155 ACTATAGGCCAGAGAGGCTGC 3' 43175 (SEQ ID NO:3)	
G2677T		80°C
2677W	5' 65221 AGTTTGACTCACCTTCCCTGC 3' 65241 (SEQ ID NO:4)

## EXAMPLE 6

### CYP3A5 Single Nucleotide Polymorphisms Genotyping

The present example describes a real-time PCR assays for  
5 the rapid detection of the most prevalent inactivating alleles of the  
CYP3A5 gene, CYP3A5\*3 and CYP3A5\*6. These methods can be  
readily applied to determine the effect of CYP3A5 genotype on inter-  
individual variability in the pharmacokinetics of CYP3A substrates.

The cytochrome P-450 3A subfamily (CYP3A) is  
10 considered the principal isoform of the CYP superfamily. CYP3A is  
abundantly expressed in the liver and gut epithelium and thus  
contributes to the high first pass extraction of a large number of  
orally administered drugs. Establishment of a causal link between  
highly variable CYP3A activity, exceeding 40% in some populations,  
15 and inter-individual variability in the bioavailability of orally  
administered medications has been the focal point of many studies.  
However, these research efforts have been limited by a lack of  
information regarding mechanisms controlling basal expression of  
CYP3A.

20 CYP3A4 and CYP3A5 constitute the majority of CYP3A  
activity in the adult. Polymorphic expression of CYP3A4 and/or

CYP3A5 could conceivably contribute to differences in basal CYP3A activity. To date, there have been no polymorphic CYP3A4 alleles linked to clinically significant differences in drug pharmacokinetics.

Recently, Kuehl et al. (2001) described two non-functional allelic variants of the CYP3A5 gene, CYP3A5 \*3 and \*6. The molecular defect in CYP3A5\*3 is a single nucleotide polymorphism (SNP; A22893G) located in intron 3. The molecular defect in CYP3A5\*6 is a SNP (G30597A) located in exon 7. More than 50% of African Americans express CYP3A5 compared to 33% of Caucasians. This led Kuehl et al. to speculate that polymorphic CYP3A5 expression may be an important genetic contributor to inter-individual and interracial differences in CYP3A-mediated drug disposition.

15

## EXAMPLE 7

### Genomic DNA

Genomic DNA can be extracted from 2 ml whole blood anti-coagulated with trisodium citrate using the QIAmp DNA Blood Midi Kit (Qiagen, Valencia, CA) according to manufacturer's

instructions. All blood samples were kept at -80 °C until DNA isolation.

5

## EXAMPLE 8

### Primer Design

Discrimination between wild-type and mutant alleles was achieved using modified PCR amplification of specific alleles described above. The modification is made to improve amplification specificity by incorporating an additional internal nucleotide mismatch near the 3' termini of the allele-specific primers. PCR primers are listed in Table 2. Oligonucleotide primers were designed based upon the published CYP3A5 sequence (Genbank #AC005020) using the online program Primer3. Oligo Toolkit™ was used to predict hairpin structures and primer-dimers. Primers were synthesized by Integrated DNA Technologies, INC. (Coralville, IA). Expected amplicon lengths were 238 bp and 273 bp for the A22893G and G30597A alleles, respectively.

20

## EXAMPLE 9

### Real-Time PCR Amplification

All reactions were carried out in a total volume of 25  $\mu$ L.

5 Reaction conditions were identical for A22893G and G30597A except where noted. Each reaction mixture contained 0.2  $\mu$ mol/l of each primer and a 1:12,500 dilution of SYBR<sup>TM</sup> Green I nucleic acid gel stain 10,000X in dimethyl sulfoxide (DMSO) (Molecular Probes); 0.2mM of dATP, dCTP, dGTP, and dTTP; 1.0 U of Taq DNA polymerase  
10 (Promega, Madison, WI); 6% DMSO; and 20 to 120 ng of genomic DNA in 1X PCR buffer (pH 8.3, 10X solution containing 100mM Tris-HCl, 500mM KCl, 15mM MgCl<sub>2</sub> and 0.01% gelatin) (Sigma, St. Louis, MO).

The amplification program for both A22893G and  
15 G30597A consisted of 1 cycle of 95°C with 120-second hold ("Hotstart") followed by 30 cycles of 95°C with 15-second hold, specified annealing temperature of 58°C with 30-second hold, and 72°C with 30-second hold. After amplification, melt analysis was performed by heating the reaction mixture from 60°C to 95°C at the  
20 rate of 0.2°C/s. A negative control without DNA template was run with every assay to assess the overall specificity.

## EXAMPLE 10

### PCR Product Analysis

5                   PCR products were analyzed as described above. Genomic DNA obtained from individuals determined by sequencing to be homo-, hetero-, and nullizygous for the \*3 allele were used to develop the CYP3A5\*3 genotyping assay. The CYP3A5\*6 allele has a frequency of approximately 6% in African-Americans, but the \*6  
10 allele was not found in Caucasians. Due to the low prevalence of the \*6 allele, the inventors were unable to identify an individual with the \*6/\*6 genotype. Thus, genomic DNA obtained from individuals determined by sequencing to be hetero- and nullizygous for the \*6 allele were used to develop the CYP3A5\*6 genotyping assay.

15

## EXAMPLE 11

### Genotyping Results

Allele-specific primers containing an additional  
20 nucleotide mismatch at the third base from the 3' termini had little effect on specific PCR product yield. However, non-specific PCR

product yield was drastically reduced to undetectable levels. Consequently, PCR conditions were optimized such that the threshold cycle (Ct) was exceeded only when specific amplification occurred (i.e., only in the presence of a primer: template match).

5                Figure 4A illustrates the results of the CYP3A5\*3 allelic discrimination assay using CYP3A5\*1/\*1 genomic DNA amplified with the common primer 3A5\*3C and either the wild-type specific primer 3A5\*3W or the mutant-specific primer 3A5\*3M. When primers 3A5\*3C and 3A5\*3W were used to amplify \*1/\*1 genomic  
10 DNA, the PCR growth curve exceeded the Ct value of approximately 25 cycles (Figure 4A), and the melting analysis (negative first derivative) yielded a characteristic sharp peak at approximately 80 °C for the product (Figure 5A). PCR growth curves remained at approximately background fluorescence (Figure 4A) when 3A5\*3C  
15 and 3A5\*3M were used to amplify \*1/\*1 genomic DNA and no distinct melting peaks were noted (Figures 4A and 5A).

Agarose gel electrophoresis yielded the expected 238 bp fragment when \*1/\*1 DNA was amplified with primers 3A5\*3C and 3A5\*3W. However, no bands were visualized after \*1/\*1 genomic  
20 DNA was amplified using primers 3A5\*3C and 3A5\*3M (data not shown). Similarly, allelic discrimination was achieved after

amplification of \*3/\*3 DNA using primers 3A5\*3C, 3A5\*3M, and 3A5\*3W (Figures 4B and 5B).

Overlapping PCR growth curves yielding similar Ct values were obtained when \*1/\*3 genomic DNA was amplified using  
5 wildtype and mutant-specific primers (Figure 4C). In addition, a distinct melt analysis peak was present after amplification with both wild-type and mutant-specific primers (Figure 5C). These results accurately predict the presence of both wild-type and mutant CYP3A5 alleles in the heterozygote control. Sequencing of genomic  
10 DNA and individual PCR products obtained from individuals homozygous, heterozygous, and nullizygous for \*3 were in perfect agreement with real-time PCR assay results. Results obtained from optimization and application of the CYP3A5\*6 genotyping assay to individuals nullizygous and heterozygous for the \*6 allele were  
15 similar to those reported for CYP3A5\*3 (data not shown). Melt curve analysis yielded a characteristic sharp peak at approximately 77 °C (Table 2).

TABLE 2

Primer Sequences For CYP3A5\*3 And CYP3A5\*6 Genotyping

Primer <sup>a</sup>	Sequence <sup>b</sup>		T <sub>m</sub> <sup>c</sup>
CYP3A5*3			80°C
3A5*3W	5' 22912	TCCAAACAGGGAAGAGAAAT 3' 22893 (SEQ ID NO:11)	
3A5*3M	5' 22912	TCCAAACAGGGAAGAGAAAC 3' 22893 (SEQ ID NO:12)	
3A5*3C	5' 22675	ACTGCCCTTGCAGCATTTAG 3' 22694 (SEQ ID NO:13)	
CYP3A5*6			77°C
3A5*6W	5' 30578	CCTTTGTGGAGAGCACTGAG 3' 30597 (SEQ ID NO:14)	
3A5*6M	5' 30578	CCTTTGTGGAGAGCACTGAA 3' 30597 (SEQ ID NO:15)	
3A5*6C	5' 30850	TGGTGGGGTGTTGACAGCTA 3' 30831 (SEQ ID NO:16)	

<sup>a</sup> W indicates wild type specific primer; M, mutant-specific primer;  
 5 C, common primer used in allelic discrimination assays.

<sup>b</sup> Nucleotides shown in bold indicate nucleotides mismatches from  
 published wild type sequence (Genbank #AC005020).

<sup>c</sup> Amplicon melt temperature (T<sub>m</sub>) obtained from melt curve  
 analysis.
